Introduction

- Late blight caused by Phytophthora infestans most economically destructive disease of potato
- Fungicides relied upon for control
- Mandipropamide key fungicide in blight programmes
- No resistance detected in natural populations
- Mechanism of resistance known (Blaum et al. 2010)

Materials & Methods

- 70 single lesion isolates selected based on genotype
- Sensitivity determined using agar plate assay
- Representative isolates tested in planta
- Sequence analysis of P/Ces3A in selection of historical isolates

Results & Discussion

- All isolates tested were sensitive to mandipropamide
- Differences between genotypes observed, with 13_A2 most sensitive
- KASP assay currently under development for early detection mutations associated with resistance

Acknowledgments

This research was been funded by the DAFM Research Stimulus Fund.
